Transport-Layer Services, Multiplexing & Demultiplexing

- Suppose a process in Host C has a UDP socket with port number 6789. Suppose both Host A
 and Host B each send a UDP segment to Host C with destination port number 6789. Will both of
 these segments be directed to the same socket at Host C? If so, how will the process at Host C
 know that these two segments originated from two different hosts?
 - yes, both segments are directed to the same socket. UDP receivers only use listen sockets, which are identified by a 3-tuple of (protocol, local IP address, local port)
 - for each received segment, at the socket interface, the OS will provide the process with the sender's IP address and port number to determine the origins of the individual segments
 - sockets are identified by a 5-tuple (source IP, source port, dest. IP, dest. port, protocol) for TCP
 - 3-way handshake: socket needs 5-tuple
 - source IP and source port put into UDP header
 - less info needed: socket needs 3-tuple as reply not necessary
 - 3-tuple identifies socket; if a reply is needed needs to be handled differently
 - this allows the two segments to be differentiated (i.e. the IP address for different hosts will differ)
- 2. Is it possible for an application to enjoy reliable data transfer even when the application runs over UDP? If so, how?
 - yes: becomes responsibility of application to handle missing/out of order packets
- 3. Indicate whether TCP or UDP (or both or neither) provide the following services to appli- cations:
- (a) Reliable data transfer between processes: TCP
- (b) Minimum data transmission rate between processes: Neither: Controlled in the link layer
- (c) Congestion-controlled data transfer between processes: TCP, sliding window
- (d) A guarantee that data will be delivered within a specified amount of time: Neither; e.g. if physical connection is broken
- (e) Preserve application-level message boundaries. That is, when a sender sends a group of bytes into a socket via a single send operation, that group of bytes will be delivered as a group in a single receive operation at the receiving application: UDP
- (f) Guaranteed in-order delivery of data to the receiver: TCP (at application layer this is true)
- 4. Why does UDP exist? Would it not have been enough to just let the user processes send raw IP packets?
 - if you want to create multi-cast application-layer protocols

- application needs finer-grained control over what data is sent and when
- if application benefits from lower latency (no round trip delay) and can tolerate some data loss e.g. real time applications, video streaming
- e.g. SNMP needs to work when network is under stress; congestion control may make this difficult
- multiplexing/demultiplexing: ports allow UDP segments to be sent to the correct process
 - transport layer is "process-to-process", while network layer is "host-to-host"
- 5. Both UDP and TCP use port numbers to identify the destination entity when delivering a message. Give two reasons for why these protocols invented a new abstract ID (port numbers), instead of using process IDs, which already existed when these protocols were designed?
- This would couple ports more tightly to operating system: process IDs may have already had their own protocols that differed from machine to machine. Wouldn't have been possible to implement a universal system
- well known port numbers established
- allows processes to use multiple ports for multiple channels of communication
- May expose information about underlying processes: poor for security (not really)
- Process IDs may change if a new process instance is spun up, but it would continue to listen through the same port number
- 6. What are the guarantees that a reliable data transfer must provide?
- guaranteed data integrity: absence of corrupted bits
- guaranteed order
- guaranteed delivery: through handling lost and corrupted packet redelivery
- 7. A process on host 1 has been assigned port p, and a process on host 2 has been assigned port q.
- (a) Is it possible for there to be two or more TCP connections between these two ports at the same time?
 - No: the 5-tuple would be the same; single socket bound to a port
- (b) Is it possible for there to be more than one TCP connection on port p of host 1 at a time?
 - Yes: 5-tuple will be different; e.g. Web servers
