# SQL

- SQL: structured query language used in relational databases
- DBMS and SQL support CRUD operations

#### - Create, read, update, delete

- Wikipedia
- provides following capabilities
  - Data definition language (DDL): define, set-up database
    - \* CREATE, ALTER, DROP
  - Data manipulation language (DML): maintain, use database
    - \* SELECT, INSERT, DELETE, UPDATE
  - Data control language (DCL): control access
    - \* GRANT, REVOKE
  - other commands: database administration, transaction control

### **Table creation**

```
    CREATE TABLE Account (
    AccountID smallint auto_increment, # surrogate key: DB auto-
increments
    AccountName varchar(100), NOT NULL, # mandatory value
    OutstandingBalance DECIMAL(10, 2) NOT NULL,
    CustomerID smallint NOT NULL,
    AccountType enum('Personal', 'Company') NOT NULL, # enumerations
    PRIMARY KEY (CustomerID), # specify primary key
```

```
8 FOREIGN KEY (CustomerID) REFERENCES Customer(CustomerID) # specify
foreign key
9 ON DELETE RESTRICT
10 ON UPDATE CASCADE
11 );
```

#### Insertion

- "string"
- 'enum'
- "" is different to NULL
- · with columns specified

```
1 INSERT INTO Customer
2 (CustFirstName, CustLastName, CustType)
3 VALUES ("Peter", "Smith", 'Personal');
```

• if columns are not specified, you must enter all columns

#### Selection

MySQL style SELECT selected keywords

```
SELECT [ALL | DISTINCT] select_expr [, select_expr ...] - List the columns (and expressions) that are returned from the query [FROM table_references] - Indicate the table(s) or view(s) from where the data is obtained - ColName AS NewColName: rename columns
```

[WHERE where\_condition] - Indicate the conditions on whether a particular row will be in the result - [LIKE "<regex>"] - used for finding records that match a pattern - %: 0+ characters - \_: single character - e.g. WHERE CustomerName LIKE "a%" finds values starting with a

[GROUP BY col\_name | expr } [ASC | DESC], ...] - Indicate categorisation of results

[HAVING where\_condition ] - Indicate the conditions under which a particular category (group) is included in

[ORDER BY col\_name | expr | position } [ASC | DESC], ...]-Sort the result based on the criteria - Default is ASC

SQL

[LIMIT offset ,] row\_count | row\_count OFFSET offset}] - Limit which rows are returned by their return order (ie 5 rows, 5 rows from row 2) - LIMIT n: limits output size - OFFSET x: skips first x records

# Aggregation

- operate on subset of values in a column of a relation (table), returning a single value
- allows you to produce derived attributes
- e.g. AVG(), COUNT(), MIN(), MAX(), SUM()
  - all of these (except COUNT()) return the result ignoring NULL values
  - COUNT() counts the number of records
- MySQL GroupBy Functions

#### e.g. count customers

```
1 SELECT COUNT(CustomerID)
2 FROM Customer;
```

e.g. average balance per customer

```
1 SELECT AVG(OutstandingBalance)
```

```
2 FROM Account
```

```
3 GROUP BY CustomerID;
```

### Group by, having

- group by groups records over a set of attributes
  - often used with aggregation
  - to put a selection condition over a group by statement, use a HAVING clause
- e.g. average balance per customer, for customers whose average balance is over 10000

```
1 SELECT AVG(OutstandingBalance)
```

```
2 FROM Account
```

```
3 GROUP BY CustomerID
```

4 HAVING AVG(OutstandingBalance) > 10000

# Joins

• Cross product: not very useful

3

```
1 SELECT * FROM Rel1, Rel2
```

• Inner/equi join: joins tables over keys using specified condition

```
1 SELECT * FROM Customer INNER JOIN Account
2 ON Customer.CustomerID = Account.CustomerID;
```

• Natual join: joins tables over keys; you don't need to specify condition, but key attributes must have identical name

1 SELECT \* FROM Customer NATURAL JOIN Account;

• Outer Join: joins tables over keys; left/right, including records that don't match the join from the other table

```
1 SELECT * FROM Customer LEFT OUTER JOIN Account
2 ON Customer.CustomerID = Account.CustomerID;
```
